

Name: Joshua Almodiel

BSIT – 3 / SEC – 1

Grid Computing is designed for high-performance, compute-intensive tasks by linking geographically dispersed computers to solve a single massive problem, whereas **Cloud Computing** focuses on providing on-demand services and resources (like storage and servers) to multiple users over the internet. While Grid scalability is often limited to the number of integrated nodes in the network, Cloud scaling is dynamic and virtually infinite, allowing resources to expand or contract instantly based on user demand. In the real world, Grid Computing is typically used for scientific research like weather modeling or drug discovery, while Cloud Computing powers everyday consumer services like Netflix, Gmail, and Spotify.
